## **Initial Words**

Yes, my slides are heavy.

I do so, because I want people to go through the slides at their own pace w/o having to watch an accompanying video.

On each slide you'll find the crucial information. In the notes to each slide you'll find more details and related information, which would be part of the talk I gave.

Have fun!

#### Name Clashes - Part 1

- The idea of oo programming leads of course to a lot of types.
- Additionally, our own code also uses other libraries, often not only from the JDK, but 3rd party libraries.
- And our library will be used by yet other code.
- · Sooner or later, we or others will get into trouble, because names of types can be reused independently.
  - Assume following situation, in which we defined our own class System and use the library commons-lang3-3.1.jar.
  - We use ArrayUtils.isEmpty() from the package org.apache.commons.lang3 of library commons-lang3-3.1.jar:

```
// <System.java>
import org.apache.commons.lang3.*;

public class System {
    public static void main(String[] args) {
        if (ArrayUtils.isEmpty(args)) {
            System. out println("You must pass some arguments!"); // Invalid! cannot find symbol 'out'
        }
    }
}
```

- However, this code won't compile! - What is going on here?

#### Name Clashes - Part 2

- The problem is, that the compiler assumes, that our class System offers the field out!
  - Sure, this is incorrect, <u>rather java.lang.System</u> offers the field <u>out</u>.
- What we have here is a name clash: we have two types with the same name, while the compiler chooses the wrong one.
  - The UML offers a way to represent the scenario in a class diagram with the «library» stereotype:

• Actually, we can easily select the correct System type for the compiler, by fully qualifying its name with the package name:

Good to know
Java imports the package java.lang into each java-file
automatically. However, here we have to fully qualify
java.lang.System to allow the compiler to tell it from
the class System in the default package.

• So, Java's types can have the same name, as long as they reside in different packages!

5

• Esp. Groovy imports more packages than only java.lang, e.g. java.util, because the types in java.util are part of the Groovy language itself.

### Packages and Package Names - Part 1

- The best way to deal with potential name clashes is to introduce own packages for own projects/libraries consequently.
  - This allows maximal control and flexibility for other developers and us as library provider!
- · So, we already unleashed the fact, that packages are used to group types logically and "shield" them from each other.
- Sure, in the beginning we have to think about <u>naming</u> our <u>package</u>.
  - Of course there are also conventions in Java, how to name packages.
- The usual naming is to use the <u>reversed domain name</u> as root, then the project name and finally other aspects.
   com.mycompany .mypackage.inout

reversed package input/output domain name name sub package

- The components of a package name must be valid Java identifiers.
- The package names are written in all lower case letters.
- Esp. if the domain name has invalid letters for Java symbols, it should be replaced with '\_'.
- If there are name clashes within a company, often substructures can be agreed upon, e.g. the region as part in the name.
- If segments of the package names are Java keywords or start with a digit, they should be prefixed with '\_'.
- packages are not allowed to begin with java or javax, those prefixes are reserved for the JDK.

## Packages and Package Names – Part 2

· Let's use the package name com.mycompany.mypackage for our discussion.

```
// <System.java>
package com.mycompany.mypackage;
import java.util.*;
public class System {
    public static void main(String[] args) {
        if (0 == args.length) {
            System.out.println("You must pass some arguments!");
        } else {
            java.lang.System.out.printf("You entered: %s%nPress enter", Arrays.toString(args));
            new Scanner(java.lang.System.in).hasNextLine();
        }
    }
}
```

- As can be seen, the package statement sets the package name. This statement must be the first statement in a java-file!
- However, the code above does <u>not yet compile</u>, the compile time error reads:
  - "Package name 'com.mycompany.mypackage' does not correspond to the file path"
- The answer is, that we have to adapt the <u>directory-structure</u> of our source code files to make the compiler happy! 7

### Packages and Package Names - Part 3

// <System.java> package com.mycompany.mypackage;

• Actually, we have to change the Java project's file structure to match the package name.

The types of the package com.mycompany.mypackage must reside in the directory com/mycompany/mypackage.

import java.util.\*;

}

Good to know
When using Maven's/Gradle's "Standard Directory Layout", the package structure starts physically below src/main/java.

That the package structure must adhere to the file structure of the file system bears a risk: the packages structure must not lead to exceedingly long file paths!

• After that change we can compile/execute System, or more exactly com.mycompany.mypackage.System:

- Mind that we chose MyProject/src/main/java as start directory.

NicosMBP:java nico\$ javac com/mycompany/mypackage/System.java NicosMBP:java nico\$ java com.mycompany.mypackage.System You must pass\_some arguments!

e { java.lang.System.out.printf("You entered: %s%nPress enter", Arrays.toString(args)); new Scanner(java.lang.System.in).hasNextLine();

The corresponding class diagram shows the naming structure of the packages nicely:

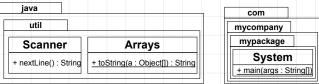

### Packages - UML Notations - Part 1

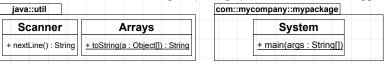

• A package can be represented as folder symbol, that shows the package name or fully qualified path within the box.

java::util com::mycompany::mypackage

- Also connectors (i.e. lines with or without arrows) can be drawn between package folders.
- We can also draw packages and sub packages as cascades symbols:
  - If a package symbol contains other symbols (classes or sub packages), the UML standard suggests to write package names into the label of the package folder symbol.

· Alternatively, the cascade can be condensed showing the package path in the label of an "aggregating package":

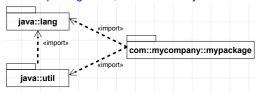

• And we can just use fully qualified class names:

# Packages – UML Notations – Part 2

• This code can also be abstracted into a package view, i.e. the bird's eye view showing package dependencies:

• Mind, that we explicitly mention the package java.lang here, although it is automatically imported into all java-files 10

## Visibility of Classes among Packages

• Although package's and sub package's names have names suggesting a hierarchical access allowance, it is not the case.

- Consider following case, although ClassB is in a sub package of ClassA, ClassB and ClassA don't see each other:

```
// <ClassA.java>
package com.mycompany.mypackage;

public class ClassA {
    public void test() {
        ClassB classB = new ClassB();
    }
}
```

```
// <ClassB.java>
package com.mycompany.mypackage.utils;

public class ClassB {
    public void test() {
        ClassA classA = new ClassA();
    }
}
```

• To make the classes visible to each other, we have to import each package respectively:

```
// <ClassA.java>
package com.mycompany.mypackage;
import com.mycompany.mypackage.utils.*;
public class ClassA {
    public void test() {
        ClassB classB = new ClassB();
    }
}
```

```
// <ClassB.java>
package com.mycompany.mypackage.utils;
import com.mycompany.mypackage.*;
public class ClassB {
    public void test() {
        ClassA classA = new ClassA();
    }
}
```

- Similar issue: classes in the default package cannot be imported into a "named" package!
- Take away: also sub packages of packages are completely different logical packages for Java!

### Java Archives (JARs) as Libraries

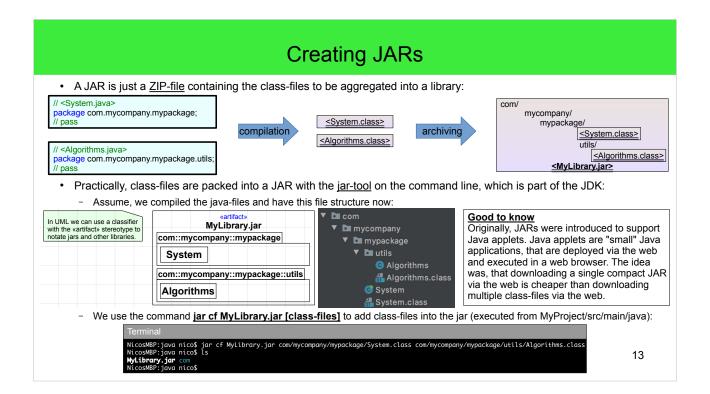

- packages are just logical groupings of types in Java, but not yet "real" libraries.
  - In programming, a library is usually a file, more formally, a physical artifact.
  - A library can be <u>versioned</u>, given to other developers and <u>tested in isolation</u>, we say it is a <u>deployment unit</u>.
- · As a matter of fact, we have already used other physical artifacts in Java, namely class-files.
- The handling of multiple class-files is <u>cumbersome</u>, therefor we can <u>aggregate</u> class-files <u>into a Java archive (JAR)</u>.
  - JARs can be used to define libraries of class-files and those <u>libraries can then be easier deployed than class-files</u>.
- · For our further discussion, assume, we have following two classes:

```
// <System.java>
package com.mycompany.mypackage;

public class System {
    // pass
}
```

```
// <Algorithms.java>
package com.mycompany.mypackage.utils;
public class Algorithms {
    // pass
}
```

- We assume the class com.mycompany.mypackage.System as we have already discussed it.
- The new package com.mycompany.mypackage.utils contains the class Algorithms, with some helper methods.
- Our task is to put these classes into a common library, i.e. a JAR.

- The jar-tool uses command line switches like the program "tar" (Tape Archiver), but it creates a ZIPfile!
  - So, instead of using the jar-tool, we could also just zip the class-files and package folders of a Java library to a zip-file.
  - However, jars are usually the better target-filetype, i.e. using the jar-extension instead of the zip-extension.

#### Inspecting and extracting JARs

- We can also have a look into the jar-file, with the jar tool's t-option, which shows the table of contents.
  - We issue the command jar tvf MyLibrary.jar on the console:
  - (The option v prints verbose information (size and creation date) of each contained file to the console.)

```
Terminal

NicosMBP:java nico$ jar tvf MyLibrary.jar

0 Wed Dec 25 23:20:46 CET 2019 META-INF/
65 Wed Dec 25 23:20:46 CET 2019 META-INF/MANIFEST.MF
870 Tue Dec 24 21:46:54 CET 2019 com/mycompany/mypackage/System.class
224 Wed Dec 25 10:41:42 CET 2019 com/mycompany/mypackage/System.class
NicosMBP:java nico$ 
NicosMBP:java nicos 
NicosMBP:java ni
```

- Obviously, MyLibrary.jar contains not only class-files, but also the directory META-INF, which contains the file MANIFEST.MF.
  - We'll discuss those files in short, they basically contain common information about the JAR. Actually MyLibrary.jar looks like so:

```
<META-INF/MANIFEST.MF>

<com/mycompany/mypackage/System.class>

<com/mycompany/mypackage/utils/Algorithms.class>

<MyLibrary.jar>
```

- We can also extract the files contained in a jar-file using the jar-tool's x-option.
  - We issue the command jar xvf MyLibrary.jar on the console:
  - As can be seen, we did a little bit more than only the **x**-option:
    - (1) We create a <u>new directory extracted</u> and cd'd into it.
    - (2) We issue jar xvf../MyLibrary.jar to extract the jar's content from the parent directory into the current directory extracted.
    - (3) The option **v** yields verbose output of the operation to STDOUT.

#### Adding Resources to JARs

- · We can also add other files into a JAR:
  - E.g. the source code of the compiled classes besides the class-files.
    - · Open source projects often create a separate JAR with sources.
  - Other resource-files, e.g. properties-files, which contain data, e.g. to configure libraries or javadoc HTML pages:

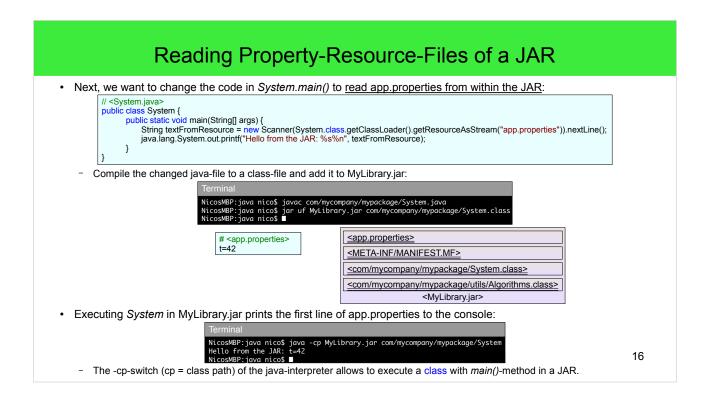

# <app.properties> t=42

- · Property-files are simple text files, that contain lines of key=value pairs.
  - Each key=value pair represents an individual property.
  - The values of the properties can then be used to configure executables/programs/libraries.
- · To do this, we use the jar-tool with jar uf MyLibrary.jar app.properties to add the properties-file into the JAR.

15

 In principle, we could add other jar-files into a JAR, but Java provides no means to load other JARs from within a JAR. To do something like this, a special class loader must be used or programmed.

 ClassLoader.getResourceAsStream() loads a file (not necessarily a class-file) from the classpath.
 The contents of a loaded jar-file is automatically part of the classpath.

# Gradle's Project Structure with Resources

• With the introduction of resources, we can further precise Gradle's Standard Directory Layout:

- (3) The <u>test code</u> should reside in projectDirectory>/src/test/<languageName>.
- (4) All the <u>resources for the tests</u> should reside in projectDirectory>/src/test/resources.

## Multiple Classes with main()-Methods

- If one or many compiled classes in a JAR have main() methods, we can execute these classes directly from the JAR!
- E.g. with these executable classes in MyLibrary.jar:

```
// <System.java>
public class System {
    public static void main(String[] args) {
        // ...
        java.lang.System.out.printf("Hello from the JAR: %s%n", textFromResource);
    }
}
```

```
// <Algorithms.java>
public class Algorithms {
    public static void main(String[] args) {
        System.out.println("Hello from the Algos!");
    }
}
```

... we can use the java command with the -cp switch addressing the JAR to execute specific "main()"-classes in a JAR:

```
Terminal

NicosMBP:java nico$ java -cp MyLibrary.jar com/mycompany/mypackage/System
Hello from the JAR: t=42
NicosMBP:java nico$ java -cp MyLibrary.jar com/mycompany/mypackage/utils/Algorithms
Hello from the Algos!
NicosMBP:java nico$ ■
```

- The -cp switch, the class path switch, is used to specify the directories and archives, in which classes are searched.
  - We will discuss this in more depth soon.

#### Manifest-Files

- We mentioned that Java supports special resources to be put into a jar-file, which enrich JARs with meta-information.
- JAR meta-information is stored in the directory <u>META-INF</u>, which is packed into the JAR at the top level.
- META-INF can contain different files storing information for different purposes, the most important file is MANIFEST.MF.
  - The jar-tool creates a <u>default-manifest</u>, which looks like this:

<MANIFEST.MF>
Manifest-Version: 1.0
Created-By: 11.0.1 (Oracle Corporation)

• We can add many additional meta-information into our own MANIFEST.MF, here a selection:

<MANIFEST.MF>
Implementation-Title: MyLibrary (Test JAR)
Implementation-Version: 3.14
Implementation-Vendor: MyCompany

- We can just save this file as META-INF/MANIFEST.MF
- Then we issue jar uvmf META-INF/MANIFEST.MF MyLibrary.jar on the command line to add the manifest to MyLibrary.jar.
  - The m-option tells the jar-tool, that we specify our own  $\underline{m}$  anifest-file as first file parameter.

#### The Main-Class of a JAR

- An interesting setting in the manifest is the specification of a main class.
- When we specify a class in a JAR to be the main class, we can directly execute this class from a jar.
  - The manifest's Main-Class property accepts this specification:

<MANIFEST.MF>

Manifest-Version: 1.0

Main-Class: com.mycompany.mypackage.System

Implementation-Title: MyLibrary (Test JAR)
Implementation-Version: 3.14

Implementation-Vendor: MyCompany

• After the MyLibrary.jar was build with this new manifest, we can execute it directly with java's -jar-option:

Terminal

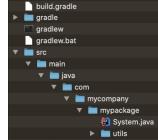

NicosMBP:java nico\$ java -jar MyLibrary.jar
Hello from the JAR: t=42
NicosMBP:java nico\$ ■

- A JAR with a Main-Class is sometimes called executable JAR.
- The Main-Class specification for a JAR (plus -jar-option) is an alternative to using the java command with the -cp-option.
  - The difference is, that we can only have one Main-Class, but with the -cp-option we can address each class with a main()-method.

• By default, Gradle creates a JAR from a Java project, which carries the name of the build.gradle-file's directory.

- Let's assume System and Algorithms incl. their package structure are represented in a Gradle project in the directory untitledProject:

• With Gradle's default configuration, and running gradlew build, we get untitledProject.jar in directory build/lib:

- · We have to do some changes to our Gradle configuration to match what we have done before with the jar-tool.
  - Besides the classes System and Algorithms we also want to add app.properties into the JAR.
  - We should <u>rename the JAR to MyLibrary.jar</u>.
- Resources such as app.properties have to be put into the directory src/main/resources to be processed by Gradle:

- By default Gradle puts the file structure under resources at the root of the internal JAR-structure, exactly as we need it!
- · As can be seen, Gradle also creates META-INF/MANIFEST.MF for us, but only with default content.

• With some changes in build gradle we rename the jar-file to be created and customize the manifest-file:

- Setting the property <u>archivesBaseName</u> specifies the name of the resulting JAR.
- The cascaded blocks jar and manifest contain a call to the Gradle-function attributes().
- attributes() accepts a list of key:value pairs, corresponding to the ones we have seen for manifest-files.
- This build gradle-file will create MyLibrary.jar, which has the manifest we have had before.

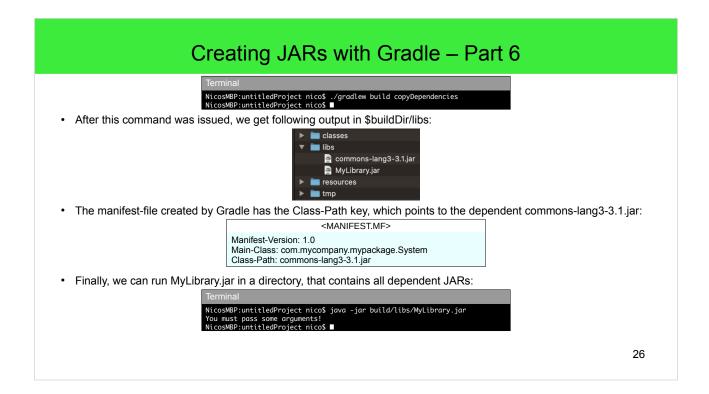

- In the beginning of the lecture, we presented code using ArrayUtils.isEmpty() of the package org.apache.commons.lang3.
  - This package is provided by the library commons-lang3-3.1.jar, so <u>it's not part of the JDK</u>.
    - (Its package name is neither prefixed with java nor javax.)

• Gradle provides means to load dependent libraries/jars from a Maven repository:

```
// <bushlesh to be a possible of the properties of the properties
```

```
// <a href="https://www.nich.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copies.the.copi
```

- Mind that we call gradlew from directory untitledProject, where build.gradle resides.

 If an OS allows to assign standard-applications to the jar-extension, we could assign the Java interpreter and start jars via a double-click on its icon as Java programs. Additionally, jars must be declared with a Main-Class in its manifest.

#### The Class Path - Part 1

- · What is a class path?
- Put simple, the class path specifies directories and individual jars, that are <u>searched for classes</u>, when a Java program is started.
- Besides the class path, some essential classes must be loaded, when a Java program starts, namely the JDK:
  - (1) So called bootstrap classes, which make up the JDK in directory jre/lib, esp. rt.jar.
  - (2) So called <u>extension classes</u>, <u>which contribute types extending the Java runtime</u> in directory <u>ire/lib/ext</u>.
  - (3) So called user classes, which make up our own classes and 3rd party classes, like those in commons-lang3-3.1.jar.
    - (3.1) User classes are searched in the <u>current directory</u>.
    - (3.2) User classes are searched in the directories/libraries/jars specified in
      - (3.2.1) the environment variable CLASSPATH (if any),
      - (3.2.2) the Class-Path specified in MANIFEST.MF (if any) and
      - (3.2.3) the <u>Java interpreter's -cp switch</u> (this is the preferred method right now).
- The take away: By default, the class path only points to the current directory!
  - This is the reason, why we have to specify the Class-Path in the manifest-file to refer the dependent jar for MyLibrary.jar.

#### The Class Path - Part 2

• Let's try specifying the class path via the environment variable CLASSPATH, therefor we remove it from the manifest-file:

• Relying on CLASSPATH, we mustn't use -jar, instead we have to set MyLibrary.jar and commons-lang3-3.1.jar there:

```
Terminal

NicosMBP:untitledProject nico$ cd build/libs
NicosMBP:libs nico$ export CLASSPATH-MyLibrary.jar:commons-lang3-3.1.jar
NicosMBP:libs nico$ java com.mycompany.mypackage.System
You must pass some arguments!
NicosMBP:libs nico$ ■
```

- (If -jar is used class loading is will be taken over by the jar file and no other sources for classes are regarded.)

#### The Class Path – Part 3

· Let's also try specifying the class path via the command line switch -cp:

Terminal

NicosMBP:libs nico\$ java -cp MyLibrary.jar:commons-lang3-3.1.jar com.mycompany.mypackage.System
You must pass some arguments!
NicosMBP:libs nico\$ ■

- Also if relying on -cp, we mustn't use -jar, instead we have to specify MyLibrary.jar and commons-lang3-3.1.jar.
  - The other way around: if -jar is used to run an executable jar, -cp is ignored.
- If -jar is used, -cp and CLASSPATH are ignored.
  - The other way around: if we want to use an executable jar (with Main-Class), we have to use Class-Path to specify the class path.
  - The Class-Path property in MANIFEST.MF overrides -cp and CLASSPATH.
- Currently, the Java community recommends using -cp, because esp. setting CLASSPATH can be tricky.
  - In a sense environment variables can be difficult to handle.
- Remark: the jar-files contained in the current path, are not automatically in the class path!
  - Instead the files in the current directory must be explicitly added. This can be done like so:

- We have to put -cp's argument into double quotes, because we have to protect it from evaluation through the terminal! The problem is the \*, which has a special meaning for resolving files for the java-tool and also has a interfering special meaning for the terminal as console (terminal-globbing).
- The trickyness of CLASSPATH lies in its global nature as environment variable. An environment variable is valid for all Java applications and could be overridden opportunistically.

# **JAR Signing**

- JARs can be signed with a digital signature with the tool-chain keytool, jarsigner and policytool.
  - The idea is to sign a JAR with a signature, which can be <u>associated with a specific issuer/vendor to maintain authenticity</u>.
  - This specific issuer/vendor should then be <u>trustworthy</u>, which is ensured by a certificate which was used to create the signature.
  - JAR signing was esp. important to guarantee the origin of a JAR containing an applet loaded dynamically by the web browser.
  - Library-code contained in signed JARs has <u>more privileges than unsigned JARs</u>.
  - A signature can also prove the <u>integrity</u> of a jar, this proves that the jar was not tampered after released by the vendor.

### static imports - Part 1

If we want to use static methods defined in another class, we can simplify the call syntax by using static imports:

```
package com.mycompany.mypackage.utils;
// <Algorithms.java>
import java.util.Scanner;

public class Algorithms {
    public static int number;

    public static int printPrompt() {
        System.out.println("Please enter a number:");
        System.out.println("The number should be greater than ten:");
        System.out.println("The number should be greater than ten:");
        Scanner inputScanner = new Scanner(System.in);
        number = inputScanner.nextInt();
        return number;
    }
```

- We just use the import keyword together with the static keyword to import all static methods of a class.
- With this import we can use all static methods of Algorithms into System, as if they were defined in System itself.
- In effect we can then call the methods of the "statically" imported class just without prefixing class name and dot.
- Similar to importing full packages, using '\*' on static imports, imports all accessible members!
  - We can also specify specific static members to be imported, e.g. only Algorithms.printPrompt():

// <System.java> import java.util.Scanner; import static com.mycompany.mypackage.utils.Algorithms.printPrompt; // pass

# static imports – Part 2

• An often seen usage of static import is importing all static methods and constants of Math, e.g. Math.sin() and Math.Pl:

```
// <Program.java>
import static java.lang.Math.*;

public class Program {
    public static void main(String[] args) {
        System.out.println(sin(PI/2));
        // >1.0
    }
}
```

• We can also statically import all members of an enum:

```
// <Program.java>
import static java.time.Month.*;

public class Program {
    public static void main(String[] args) {
        System.out.println(DECEMBER);
        // >DECEMBER
    }
}
```

- · Restrictions:
  - static imports cannot be used for classes of the default package! It is really meant to shorten the syntax for long package names.
- <u>Personal recommendation</u>: <u>minimize using static imports</u>, it can hide the origin of esp. methods!
